For this purpose, there are system-wide accessibility settings baked in Android, and you can control them through the Accessibility section of the Settings app. This is right at the bottom near the about phone and developer settings. Your own device can have many, many more - the LG G3, for example, has enough to fill the post all its own - but as long as you have Android, you should at least have them. Let's open it and explore it together. Services: Many apps can take advantage of Google's accessibility APIs to better serve their users and to make our phones more. If you checked Tasker or AutoVoice and were asked to turn them on on the Accessibility tab, here's where they appear. Here's where to turn them off if you decide you no longer need their services. By default, there is only one service in the list of services: TalkBack. TalkBack: Talkback provides verbal, audio and vibrational cues for visually impaired users by acting as a built-in screen reader. It can be turned on or off here, and you have been given a shortcut to TalkBack settings, which include changing the volume and reading height, when speech should and should not stop, and what feedback should be provided to vibrations even during touch. TalkBack progress features like Explore on Touch can be amazing, but they can also observe and repeat sensitive information such as credit card information and passwords. When using these features, connect to the environment and volume. Descriptions: This will allow closed subtitles at the system level, allowing videos to adjust the user's style/description size settings when applicable. This was introduced in Kit Kat, so phones still on Jelly Bean or ICS may not support subtitles at the system level. Magnifies: With magnifying, we're getting into accessibility features that could prove useful to Android owners who don't have a disability. Triple tap to zoom or zoom in, and triple tap and hold to magnify what was under your finger. Useful for older users or for use with apps that don't scale well on smaller devices, such as Vudu. Great text: This one is quite an explanation in itself. If you click this, all text will immediately become larger across your device. No finesse, no setting of a certain size, just plain or large. This is useful for those who have problems with small text, whether they are very visually impaired or just need a little help without reading glasses. Power button ends call: Another quick this one can also be useful to a wide range of users. If you want a physical button to end a call, this is your answer. Just be. Be. from that if you're someone who often turns on the screen during a call. Automatic rotation: I have no idea why this is here, but it is. This is duplicating the auto-rotate setting in part of the screen and works the same way. Check to enable, make sure the screen rotation is locked. Talking passwords: This could understandably come back very quickly, so enable only if when you absolutely need it. Accessibility Shortcut: This will allow you to quickly enable accessibility features, even when your device is locked. This can come in handy on tablets with multiple accounts and on text-to-speech: This will take you to a sub-menu that will allow you to choose the text-speak engine of your choice. Google's default setting, but there's a wide range of replacement services that can be used. You can also choose the speed of speech and engage in languages if you use more than one. Tap and hold the delay: This will change the length of time you have to hold for any press and hold actions. For those with dexterity issues, a longer delay can help while navigating their device. Although there are many settings here, there are a few that I do not see. The one that screams at me the most is the one I'd actually use: inversion. Flipping the screen so users can have white text on black backgrounds for apps can help improve readability. For those who are accustomed to dark environments or have photophobia - which can accompany eye strain or migraines - twisting and darkening the screen is a godsend. Fortunately, it seems that the inversion comes in Android L. And, again, your phone may have additional accessibility settings. These are just the bare minimum you can expect to see in Android.
